ABSTRACT

Objective: Diabetes Mellitus is group of common metabolic disorders that share the phenotype of hyperglycemia. Type 2 diabetes mellitus is a familial disease with a lifetime risk of 40% if one parent has Type 2 diabetes. Overweight is the second risk factor for type 2 diabetes mellitus. Till now, very few studies have shown early outcome of genetic transmission on cardiac autonomic activity among healthy offsprings with parental type 2 diabetes mellitus. Thus, the aim of this study was to examine the impact of parental Type 2 diabetes on autonomic nervous system and to determine whether autonomic neuropathy is present and its association with glycemic status, weight and height.

Method: The cross-sectional study of Height, Weight, Glycemic status and Cardiovascular Autonomic Functions was carried out in 30 healthy offsprings of Type 2 Diabetic Parents (Study group) and 30 healthy offsprings of Nondiabetic Parents (Control group) in the age range of 18 - 21 years.

Results: There is insignificant decrease in parasympathetic functions and insignificant increase in Fasting and Post-load Blood Glucose in Study Group. There significant increase in weight, and height of subjects of Study Group.

Conclusion: Our observations indicate that subclinical autonomic dysfunction may develop without the presence of long-term hyperglycemia in family members of type 2 diabetic subjects; Insulin resistance is a function of fat mass & because increasing body weight in the industrialized world has been accompanied by earlier presentation or acceleration of Type 2 Diabetes Mellitus. Different factors (including hyperglycemia) could subsequently affect the expression of the genes and influence the progression of neuropathy.

Keywords: Parasympathetic Functions, Nondiabetic Offsprings, Glycemic Status

INTRODUCTION

Diabetes Mellitus is a group of common metabolic disorders that share the phenotype of hyperglycemia. Several distinct types of Diabetes Mellitus exist and are caused by a interaction of genetics and environmental factors. Type 2 diabetes mellitus is a familial disease with a lifetime risk of 40% if one parent has Type 2 diabetes. Overweight is the second risk factor for type 2 diabetes mellitus. Now a day Type 2 Diabetes Mellitus is being diagnosed more frequently in children and young adults, particularly in obese adolescents. Insulin resistance is a function of fat mass & because increasing body weight in the industrialized world has been accompanied by earlier presentation or acceleration of Type 2 Diabetes Mellitus. Possibility of early alterations in neural cardiovascular regulation in healthy offsprings of diabetic patients has been addressed recently. Hyperinsulinemia and insulin resistance are pervasive features of obesity, increasing with weight gain and diminishing with weight loss. Longitudinal studies have revealed significant correlation between autonomic dysfunction and risk of developing Type2 diabetes Mellitus. Aim of this study was to determine relation between Height, Weight, glycemic status and Cardiovascular Autonomic Functions in the offsprings of Type 2 Diabetic Parents & compare them with that offsprings of Nondiabetic parents.

MATERIALS AND METHODS

The cross-sectional study was carried out in 30 healthy offsprings of Type 2 Diabetic Parents (Study group) and
30 healthy offsprings of Nondiabetic Parents (Control group) in the age range of 18 - 21 years randomly selected among 1st MBBS students of BLDEU’s Shri B M Patil Medical College, Bijapur. The ethical clearance for the study was obtained from ethical committee.

Method of Collection of Data:

Study group: This group consists of 30 normal healthy male medical students (Offsprings of Type 2 Diabetic Parents) of BLDEU’s Shri B.M.Patil Medical College, Bijapur.

Control group: This group consists of 30 age matched normal healthy male medical students (Offsprings of Nondiabetic Parents) of BLDEU’s Shri B.M.Patil Medical College, Bijapur. Each subject taking part was explained about the procedure to be adopted in the research. All the subjects after thoroughly understanding the procedures to be adopted signed an informed consent form provided to them. All subjects underwent thorough clinical examination.

Inclusion criteria: Only healthy subjects of Indian origin were included in the study. The subjects without signs of cardiovascular, endocrinological, neurological, hematological & inflammatory diseases were selected for the study. The apparent health status of the subject was determined through clinical examination and history taking.

Exclusion criteria: The subjects with any of following findings were excluded from study.

1) Evidence of hypertension (systolic blood pressure more than 150 and diastolic blood pressure more than 90 mm Hg).

2) Subjects having diabetes mellitus, bronchial asthma, giddiness on standing, syncopal spells, visual disturbances, nocturnal diarrhea.

3) Subjects receiving drugs that are known to interfere with cardiac function or respiratory functions such as beta blockers, sympathomimetic drugs, vasodilators and diuretics.

4) Associated disease or conditions known to affect autonomic function like Guillain Barre syndrome, Poliomyelitis, Diphtheria, Tuberculosis, Syphilis, Amyloidosis, Chronic renal failure.

5) Subjects with history of alcohol intake/ tobacco consumption in any form.

6) Any disease condition affecting the autonomic nervous system.

Following parameters were recorded in each subject:

Record of Physical Anthropometry of subjects:
A) Height (in cms): This was measured with the subject in standing position without his shoes, nearest to 0.1cms.

B) Weight (in kgs): The subjects were weighed in standardized machine with minimum of their clothing’s, nearest to 0.1 kgs

C) Body Surface area & Body Mass Index were measured.

Record of Physiological parameters: Pulse rate (beats per minute), Blood Pressure (SBP and DBP in mmHg), Respiratory Rate (Cycles/Minute) were recorded.

Record of Autonomic Function Parameters

The subject was informed about the procedure. Consent from each subject was taken before recording. For each parameter, three readings were taken. Mean of three readings was taken for calculation. The following parasympathetic function parameters were recorded using Computerised 4 channel Physiopac performed as per methods described by Sir Roger Bannister.

I. Heart rate response to Valsalva Maneuver
II. Heart rate response to deep breathing
III. Immediate heart rate response to standing

Glycemic status of an individual is determined by Oral Glucose Tolerance Test. 1. Fasting blood glucose. 2. Two hours After Glucose Load (Consisting of 75g glucose anhydride in 300ml of water ingested over the course of 5 minutes.

Statistical analysis: All values are presented as Mean ± Standard Deviation (Mean ± SD). Comparison of mean values of parameters between Control and Study group is done by Z test. Correlation between various autonomic function parameters & glycemic status is done by correlation. A p value of 0.05 or less was considered as statistically significant.

DISCUSSION

The cross-sectional study is carried in 60 normal healthy medical students (Offsprings of Type 2 Diabetic Parents n=30; and Nondiabetic Parents n=30) in the age group of 18-21 years. In our study we have recorded various physical & physiological parameters in both Control and Study groups. Parasympathetic function is assessed by heart rate response to Valsalva maneuver, heart rate response to deep breathing, immediate heart rate response to standing. Glycemic status was assessed by Oral Glucose Tolerance Test.

Heart rate response to Valsalva maneuver: Our study showed insignificant decrease (p=0.222) in mean valsalva ratio in study group compared to control group. Our findings are in accordance with earlier studies done by C. Hauerslev Foss et al4. Heart rate response to Valsalva maneuver appear to be more sensitive parameters to detect autonomic dysfunction amongst the three Parasympathetic function tests.

Heart rate response to deep breathing: There is insignificant (p=0.132) decrease in the heart rate variation during deep breathing in Study Group compared to Control Group. Our study is in accordance with studies done by C. Hauerslev Foss et al4.

Heart rate response to Standing (30:15 ratio): Heart rate response to standing in normal subjects consists of tachycardia maximum around 15th beat followed by relative bradycardia around 30th beat after standing22. These hemodynamic responses are mediated by baroreceptors. In our study we found a insignificant (p=0.335) decrease in the immediate heart rate response to standing in Study Group compared to Control Group. Our study is in accordance with studies done by C. Hauerslev Foss et al4.

Glycemic Status: There is insignificant increase in the Fasting Blood Glucose and Postload Blood Glucose in Study Group compared to Control Group. Our study is in accordance with studies done by I.N.Migdalis et al5, Frontoni S et al6. Our results are not in agreement with C. Hauerslev Foss et al4.

Height & Weight: There is significant increase in weight (p=0.04) and height (p=0.04) Study Group compared to Control Group. Our study is in accordance with studies done by C. Hauerslev Foss et al4.

CONCLUSION

This cross sectional study shows that offsprings of Type 2 Diabetic parents have increased prevalence of cardiac autonomic neuropathy compared with offsprings of nondiabetic parents. The results indicate that early autonomic neuropathy may be present without the influence of long-term hyperglycemia and we suggest that autonomic neuropathy may be part of a genetic syndrome rather than a secondary complication of diabetes.
